증례 (**or** 수술술기) : The author performed an epidemiologic study in Jeju Island, South Korea using data prospectively collected from 2002 until 2006. Jeju is geographically isolated from the main land and patients with hip fractures typically require hospitalization, which makes epidemiologic studies easier and more reliable than those on other fracture types. This prospective study was performed to estimate morbidity and mortality after hip fracture among patients more than 50 years old, in Jeju island, South Korea.
