증례 (or 수술술기) : The annular ligament in the elbow has been proposed to provide the lateral and posterolateral stability in conjunction with the lateral collateral ligament. However, the importance of the annular ligament has not been defined comprehensively. The annular ligament has to be cut during the surgery of radial head or neck fractures, but there has been no definite operative guideline whether it should be repaired. We performed open reduction and internal fixation with loose indirect repair of the annular ligament, not doing tight direct repair, and analyzed the effect of it both radiologically and clinically.

acknowledgment :

annular ligament, radial head and neck fracture, indirect repair
